The Series 7116B Spirahelic® Pressure Indicating Transmitter simultaneously provides local indication on a large, easily read analog scale while also converting that pressure into a standard two wire, 4-20 mA signal for ranges from 0-60 to 0-600 psi. Positive compatible gas pressure is measured to the accuracy of ±0.5% of full scale. The gage employs a unique triple helix Bourdon tube for precision measurement of compatible gases and liquids. The direct drive design reduces friction and mass, resulting in exceptionally good responsiveness, repeatability and accuracy. Because there are no gears, springs linkages or other complicated mechanisms, wear is practically eliminated. The electrical signal and conditioning is produced by a piezoresistive pressure cell. A 316 stainless steel connection block features convenient dual 1/4˝ female NPT and 1/2˝ male NPT pressure connection. Pressure block also includes integral filter plug to keep dirt out. Safety is assured with solid front case design and rear blowout hole.

**INSTALLATION**

1. Select a location free from excessive vibration where the temperature limits of 20 to 120°F (-6.67 to 48.9°C) will not be exceeded. Mounting surface should be vertical to match the position in which all standard gages are calibrated. Avoid locations in direct sunlight which may cause accelerated discoloration of the clear acrylic lens or where exposure to oil mist or other airborne vapors could likewise result in lens damage. Make sure that the case relief area on the rear is not obstructed. This hole is designed to direct pressure rear-ward in the event of a failure of the Bourdon tube element. See complete safety recommendations at the end of this bulletin.

2. See Fig. A for mounting hole instructions.

**SPECIFICATIONS**

**GAGE SPECIFICATIONS**

- **Service:** Compatible gases & liquids.
- **Wetted Materials:** Inconel® X-750 Alloy Bourdon Tube, Type 316L SS connection.
- **Housing:** Black polycarbonate case and clear acrylic cover.
- **Accuracy:** Grade 2A (0.5% F.S.).
- **Stability:** ± 1% F.S./year.
- **Pressure Limit:** 150% of full scale. Gage will maintain its specifications for overpressures up to 150% maximum range. Normal operation should be between 25% and 75% of full scale.
- **Temperature Limits:** 20 to 120°F (-6.67 to 48.9°C).
- **Size:** 4-1/2˝ (114.3 mm) dial face. Design conforms to ASME B40.1.
- **Process Connections:** Dual size 1/4˝ male NPT / 1/4˝ female NPT pressure connection.
- **Weight:** 29.5 oz (836.3 g).

**TRANSMITTER SPECIFICATIONS**

- **Accuracy:** 0.5% F.S.
- **Temperature Limits:** 20 to 120°F (-6.67 to 48.9°C).
- **Thermal Effect:** ± 0.025% F.S./°F (0.045% F.S./°C).
- **Power Requirements:** 10-35 VDC (2 wire).
- **Output Signal:** 4-20 mA DC.
- **Zero & Span Adjustments:** Externally accessible potentiometers.
- **Loop Resistance:** DC, 0-1250 ohms.
- **Current Consumption:** DC, 38 mA max.
- **Electrical Connections:** Screw Terminals.
- **Mounting Orientation:** Vertical.
- **Agency Approvals:** CE.
3. A 1/4” female NPT 1/2” male NPT pressure connection is furnished to allow you the choice of vertical (from below the gage) or horizontal piping. The unused port is plugged. When changing the pressure connection from the vertical to the horizontal position, use a minimal amount of thread sealant. Too much could block the internal pressure passage. **CAUTION:** When installing fittings or pipe always use a second wrench on the 7/8” connection block. **DO NOT** allow torque to be transmitted from the block to the case.

**ELECTRICAL CONNECTIONS**

**CAUTION:** Do not exceed specified supply voltage ratings. Permanent damage not covered by warranty will result. This unit is not designed for 120 or 240 volt AC line operation.

Electrical connections to the Series 7116B Spirahelic® Pressure Indicating Transmitter are made on the backside of the enclosure unit. Feed stripped and tinned leads to the terminal block screws marked 1 and 2. Refer to figure B for locations of the terminal block, span and zero adjustments.

**Wire Length** - The maximum length of wire connecting transmitter and receiver is a function of wire size and receiver resistance. Wiring should not contribute to more than 10% of receiver resistance to total loop resistance. For extremely long runs (over 1000 feet), choose receivers with higher resistances to minimize size and cost of connecting leads. When the wiring length is under 100 feet, lead wire as small as 22 AWG can be used.

**2-Wire Operation** - An external power supply delivering 10-35 VDC with minimum current capability of 40 mA DC (per transmitter) must be used to power the control loop. See Fig. C for connection of the power supply, transmitter, and receiver. The range of the appropriate receiver load resistance (RL) for the DC power supply voltage available is expressed by the formula and graph in Fig. D. Shielded two wire cable is recommended for control loop wiring. If grounding is required use negative side of control loop after receiver. See Fig. C.

**Pneumatic Calibration Test**

Use a dead weight tester or certified test gage having accuracy of 1/4% or better for ANSI Grade A gages, 0.1% or better for ANSI Grade 2A gages. The test gage range should be comparable to the range of the Series 7116B Spirahelic® Pressure Indicating Transmitter gage being checked. Connect lines from the two instruments to a tee and the third line from the tee to a controllable source of pressure. Apply pressure slowly so that the pressure equalizes throughout the system, compare readings. If the gage being tested is found to need calibration return it to the address on page 3.
Pressure Ranging
Each standard Series 7116B Spirahelic® Pressure Indicating Transmitter is factory calibrated to produce 4 mA at zero scale reading and 20 mA at full scale reading. The following procedure should be used if the pressure versus output signal relationship needs to be checked.

1. With the unit connected to the companion receiver per preceding instructions, insert an accurate milliammeter, with a full scale reading of approximately 30 mA, in series with the current loop. A controllable pressure source capable of achieving the desired range should be connected to the pressure port of the transmitter and teed into an accurate reference pressure gage or manometer. The instrument must be ranged in the same position in which it is going to be used. Vertical mounting is recommended.

2. Apply electrical power to the system and allow it to stabilize for 10 minutes.

3. With no pressure applied to the transmitter, adjust “Zero” adjustments so that loop current is 4 mA.

4. Apply full range pressure and adjust loop current to 20 mA using “Span” adjustments.

5. Relieve pressure and allow transmitter to stabilize for 2 minutes.

6. Zero and Span adjustments may be interactive so repeat steps 3 thru 5 until zero and full range pressures consistently produce loop currents of 4 and 20 mA respectively.

7. Remove the milliammeter from the current loop and proceed with final installation of the transmitter and receiver.

MAINTENANCE
No lubrication or periodic servicing is required after final installation of the Series 7116B Spirahelic® Pressure Indicating Transmitter. A periodic check of calibration is recommended following the procedure under pressure ranging and pneumatic calibration test. Except for this, these transmitters are not field serviceable and should be returned, freight prepaid, to the factory if repair is needed. Be sure to include a clear description of the problem plus any application information available.

Repairs
Field repair should not be attempted and may void warranty. Gages needing calibration or other service should be returned prepaid to:

Dwyer Instruments, Inc.
ATTN: Repair Department
102 Indiana Highway 212
Michigan City, IN 46360

Multiple Receiver Installation
An advantage of the standard 4-20 mA DC output signal used in Series 7116B Spirahelic® Pressure Indicating Transmitters is the compatibility with a wide range of receivers. Devices such as the A-701 Digital Readout, A-702 Digital Readout with alarms, an analog panel meter, a chart recorder and other process control equipment can be operated simultaneously. It is only necessary that all devices be designed for a standard 4-20 mA input, the proper polarity of input connections must be observed and the combined receiver resistance's must not exceed the maximum for the current loop. If the receiver indicates a negative or down scale reading, the signal input leads are reversed.
The following material is excerpted from a standard titled "Gauges-Pressure Indicating Dial Type-Elastic Element (AN-SI/ASME B40.1-1985)" as published by The American Society of Mechanical Engineers, 345 East 47th St., New York, NY 10017. This information is furnished to assist the user of Spirahelic® gages in properly evaluating their suitability for the intended application and conditions.

4 SAFETY

4.1 Scope

This Section of the Standard presents certain information to guide users of pressure gauges and manufacturers toward minimizing the hazards that could result from misuse or misapplication of pressure gauges with elastic elements. The user should become familiar with all sections of this Standard, as all aspects of safety cannot be covered in this Section. Consult the manufacturer's instructions for advice whenever there is uncertainty about the safe application of a pressure gauge.

4.2 General Discussion

4.2.1 Adequate safety results from intelligent planning and careful selection and installation of gauges into a pressure system. The user should inform the supplier of all conditions pertinent to the application and so that the supplier can recommend the most suitable gauge for the application.

4.2.2 The history of safety with respect to the use of pressure gauges has been excellent. Injury to personnel and damage to property have been minimal. In most instances, the cause of failure has been misuse or misapplication.

4.2.3 The pressure sensing element in most gauges is subject to the following effects: mechanical stress, and application, exist where the possibility of catastrophic failure is present. Pressure regulators, chemical (diaphragm) seals, pulsation dampers, and similar devices are available for use in these potentially hazardous systems. The hazard potential increases at higher operating pressures.

4.2.4 The following systems are considered potentially hazardous and must be carefully evaluated:

(a) compressed gas systems
(b) vacuum systems
(c) systems containing hydrogen or free hydrogen atoms
(d) corrosive fluid systems (gas and liquid)
(e) pressure systems containing any explosive or flammable mixture or medium
(f) steam systems
(g) non-steady pressure systems
(h) systems where high overpressure could be accidently applied
(i) systems wherein interchangeability of gauges could result in hazardous internal contamination or where lower pressure gauges are used in higher pressure systems
(j) systems containing radioactive or toxic fluids (liquids or gases)
(k) systems installed in a hazardous environment

4.2.5 When gauges are to be used in contact with media having known or uncertain corrosive effects or known to be radioactive, random or unique destructive phenomena can occur. The user should always furnish the supplier or manufacturer with information relative to the application and solicit his advice prior to installation of the gauge.

4.2.6 Fire and explosions within a pressure system can cause pressure element failure with very violent effects, even to the point of completely disintegrating or melting the gauge body. Violent effects are also produced when failure occurs due to:

(a) hydrogen embrittlement
(b) contamination of a compressed gas
(c) formation of acrides
(d) weakening of soft solder joints by steam or other heat sources
(e) weakening of soft soldered or silver brazed joints caused by heat sources such as fires
(f) corrosion
(g) faulty construction
(h) mechanical shock
(i) shock from transportation

Failure in a compressed gas system can be expected to produce violent effects.

4.2.7 Modes of Elastic Element Failure. There are four basic modes of elastic element failure, as follows:

4.2.7.1 Fatigue Failure. Fatigue failure caused by pressure induced stress generally occurs from the inside to the outside along a highly stressed edge radius, appearing as a small crack that propagates along the edge radius. Such failures are usually more critical with compressed gas media than with liquid media. Fatigue cracks usually release the media fluid slowly so that case pressure buildup can be averted by providing pressure relief openings in the gauge case. However, in high pressure elastic elements where the yield strength approaches the ultimate strength of the element material, fatigue failure may resemble explosive failure.

A restrictor placed in the gauge pressure inlet will reduce pressure surges and restrict fluid flow into the partially opened Bournon tube.

4.2.7.2 Overpressure Failure. Over pressure failure is caused by the application of internal pressure greater than the rated limits of the elastic element and can occur when a low pressure gauge is installed in a high pressure port or system. The effects of overpressure failure, usually more critical in compressed gas systems than in liquid filled systems, are unpredictable and may cause parts to be propelled in any direction. Cases with pressure relief openings will not always retain expelled parts.

Placing a restrictor in the pressure gauge inlet will not reduce the immediate effect of failure, but will control flow of escaping fluid following rupture and reduce potential of secondary effects.

It is generally accepted that solid front cases with pressure relief back will reduce the possibility of parts being projected forward in the event of failure. The window alone will not provide adequate protection against internal case pressure buildup, and can be the most hazardous component.

4.2.7.3 Corrosion Failure. Corrosion failure occurs when the elastic element has been weakened through attack by corrosive chemicals present in either the media inside or the environment outside it. Corrosion failure may occur as pinhole leakage through the elements walls or early fatigue failure due to stress cracking brought about by chemical deterioration or embrittlement of the element material.

A chemical (diaphragm) seal should be considered for use with pressure media that have a corrosive effect on the elastic element.

4.2.7.4 Explosive Failure. Explosive failure is caused by the release of explosive energy generated by a chemical reaction such as can occur with adiabatic compression of oxygen or carbon dioxide. It is generally accepted that there is no known means of predicting the magnitude or effects of this type of failure. For this mode of failure, a solid wall or partition between the elastic element and the window will not necessarily prevent parts being projected forward.

4.2.8 Pressure Connection. See recommendations in paragraph 3.3.4.

4.3 Safety Recommendations.

4.3.1 Operating Pressure. The pressure gauge selected should have a full scale pressure such that the operating pressure occurs in the middle half (25 to 75%) of the scale. The full scale pressure of the gauge selected should be approximately two times the intended operating pressure. Should it be necessary for the operating pressure to exceed 75% of full scale, contact the supplier for recommendations. This does not apply to test, retarded, or suppressed scale gauges.

4.3.2 Use of Gauges Near Zero Pressure. The use of gauges near zero pressure is not recommended because the accuracy, tolerance may be a large percentage of the applied pressure. If for example, a Bourdon gauge B8 is used to measure 6 psi, the accuracy of measurement will be ±3 psi, or ±50% of the applied pressure. In addition, the scale of a gauge is often laid out so that the user can result in further inaccuracies when measuring pressures that are a small percentage of the full scale.

For the same reasons, gauges should not be used for the purpose of indicating that the pressure in a tank, autoclave, or other similar unit has been completely exhausted to atmospheric pressure. Depending on the accuracy and the span of the gauge and the possibility that takeup is incorporated at the beginning of the scale, hazardous pressure may remain in the tank even though the gauge is indicating zero pressure. A venting device must be used to completely reduce the pressure before unlocking covers, removing fittings, or performing other similar activities.

4.3.3 Compatibility With the Pressure Medium. The elastic element is the weakest bonded member, which is needed under high stress conditions and must, therefore, be carefully selected for compatibility with the pressure medium. Some of the common element materials is imperative to every type of chemical attack. The potential for corrosive attack is established by many factors, including concentration, temperature, pressure, and contamination of the medium. The user should inform the gauge supplier of the installation conditions so that the appropriate elements can be selected.

4.3.4 Expansion of the other factors discussed above, the capability of a pressure element is influenced by the design, materials, and fabrication of the joints between its parts.

Common methods of joining are soft soldering, silver brazing, and welding. Joints can be affected by temperature, stress, and corrosive media. Where application questions arise, these factors should be considered by the user and manufacturer.

4.3.5 Some special applications require that the pressure element assembly have a high degree of leakage integrity. Special arrangement should be made between manufacturer and user to assure that the allowable leakage rate is not exceeded.

4.3.6 Cases

4.3.6.1 Cases, Solid Front. It is generally accepted that a solid front case per paragraph 3.3.1 will reduce the possibility of parts being projected forward in the event of element assembly failure. An exception is explosive failure of the elastic element.

4.3.6.2 Cases, Liquid Filled. It has been general practice to use glycerine or silicone filling liquids. However, these fluids may not be suitable for all applications. They should be avoided where strong oxidizing agents including, but not limited to, oxygen, chlorine, nitric acid, and hydrogen peroxide are involved. In the presence of oxidizing agents, potential hazard can result from chemical reaction, ignition, or explosion. Completely fluorinated or chlorinated fluids, or both, may be more suitable for such applications.

The user shall furnish detailed information relative to the application of gauges having liquid filled cases and solicit the advice of the gauge supplier prior to installation.

Consideration should also be given to the instantaneous hydraulic impact that may be created by one of the modes of failure outlined in paragraph 4.2.7. The hydraulic effect due to pressure element failure could cause the window to be projected forward even when a case having a solid front is employed.

4.3.7 Restrictor. Placing a restrictor between the pressure connection and the elastic element will reduce the immediate effect of failure, but will help control flow of escaping fluid following rupture and reduce the potential of secondary effects.

4.3.8 Specific Service Conditions

4.3.8.1 Specific applications for pressure gauges exist where hazards are known. In many instances, requirements for design, construction, and use of gauges for these applications are specified by state or federal agencies or Underwriters Laboratories, Inc. Some of these specific service gauges are listed below. The list is not intended to be all inclusive and the user should always advise the supplier of all application details.

4.3.8.2 Acetylene Gauges. A gauge designed to indicate acetylene pressure. It shall be constructed using materials that are compatible with commercial acetylene.

4.3.8.3 Ammonia Gauge. A gauge designed to indicate ammonia pressure and to withstand the corrosive effects of ammonia. The gauge may bear the inscription AMMONIA on the dial. It may also include the equivalent saturation temperature scale markings on the dial.

4.3.8.4 Chemical Gauge. A gauge designed to indicate the pressure of corrosive or high viscosity media. The primary material(s) in contact with the pressure medium may be identified on the dial. It may be equipped with a chemical (diaphragm) seal, pulsation damper, or pressure relief device, or a combination. These devices help to minimize potential damage to the pressure element and apparatus in the event of gauge failure. They may, however, also reduce accuracy or sensitivity, or both.

4.3.8.5 Oxygen Gauge. A gauge designed to indicate oxygen pressure. "Oxygen Pressure" shall comply with Level IV (see Section 9). The dial shall be clearly marked by a universal symbol and/or USE NO OIL in red color (see paragraph 6.1.2.1).

4.4 Reuse of Pressure Gauges

It is not recommended that pressure gauges be moved from one application to another. Should it be necessary, however, the following must be considered:

4.4.1 Chemical Compatibility. The consequences of incompatibility can range from contamination to explosive failure. For example, moving a service gauge to oxygen service can result in explosive failure.

4.4.2 Partial Fatigue. The first installation may involve pressure pulsation that has expanded most of the gauge life, resulting in early fatigue in any one of the common element materials is imperative to every type of chemical attack. The potential for corrosive attack is established by many factors, including concentration, temperature, and contamination of the medium. The user should inform the gauge supplier of the installation conditions so that the appropriate elements can be selected.

4.4.3 Corrosion. Corrosion of the pressure element assembly in the first installation may be sufficient to cause early failure in the second installation.

4.4.4 Other Considerations. When reusing a gauge, all guidelines covered in this Standard relative to application of gauges should be followed in the same manner as when a new gauge is selected.
